Reliability “insurance” is included in utility rates

♦ Reserve requirements for generating capacity
♦ N-1 contingencies in transmission
♦ Redundant equipment and systems and hardened assets built into distribution system

How much should customers pay to ensure (highly) reliable electric service?

Conversely, how much risk (of outage) should customers bear in order to keep rates down?
Foundational Economics

\[\text{Incremental benefit (demand)} = \text{Incremental cost (supply)}\]

- Slightly different context than traditional cost-benefit analysis
- Costs can be traced to investment borne by the electric utility
- Benefits may be realized by the utility via efficiency gains or factors which lower overall production costs (and then passed in whole or in part to customers), but...
- ... benefits are frequently realized directly by customers in the form of reduced frequencies and durations of outages and measured by the value they place on avoiding outages
Value of Lost Load

Demand curve for incremental investment may be approximated by customer *willingness to pay* (WTP) or *the value that customers place on avoiding losing load* (VOLL).

- VOLL = survey-based estimate of value to various categories of customers by duration of outage event (Berkeley National Lab / DOE, 2009)
  - Total VOLL higher for longer duration events, but lower on unserved kWh basis
  - Lower for Residential than Commercial and Industrial (which face lost revenues)

- VOLL can be as high as $95,000 for an 8 hour outage event during a summer day for a large commercial or industrial customer.
**Value of Lost Load**

Much higher than cost – and utility would not charge rates that are equal to VOLL – but indicator of potential benefits

VOLL For “Anyday” (Average)
Berkeley / DOE Study (2009)

Cost of generating reserves are currently included in the cost of power

Current RA (planning reserve margin) requirements typically based on “1-day-in-10-year” standard
- Not defined uniformly (0.1 event per year vs. 2.4 hours per year)
- Has not been updated in decades

Translates into 10% or 15% reserve margin

Source: Analysis of FERC Form 1 data; breakdown between fuel and power supply and electric delivery were rounded for ease of presentation. Breakdown of fuel and power supply based on panel of utility data.
Reserve Requirements
Costs and Benefits

Are RR set so incremental costs = incremental benefits?

♦ “Reasonable level”: probability of failure to carry load 1 day in 8 – 10 years. (Calabrese, 1947; Watchorn, 1950)

♦ Reserve requirements could be lower than 1-in-10 if based on economics of incremental benefits (VOLL) = incremental costs. (Telson, 1973; PGE 1990)

♦ Optimal reserve requirements may be higher than 1-in-10 if all costs are considered
  • Production related reliability costs
  • Emergency purchase costs
  • Unserved energy costs (EUE and VOLL) (Astrape Consulting and The Brattle Group, NRRI, 2011)
Reserve Requirements Costs vs. VOLL

- Benefit of optimal RR % = overall lower cost to customers

- Estimated impact of EUE (VOLL) is relatively low – because risk of firm load shed events is relatively low

- Major impact of reduced RR is more on cost of purchases of power (emergency) than value of lost load.

Investments In Electric Delivery

- Upgrades in T&D system, AMI and SG
  - Net book value of IOUs ~$300 billion (not replacement value)
  - Upgrading aging distribution system + smart grid investment over next 20 years ~$600 billion

- Additional investments required to bring renewables (wind) to load centers
  - New transmission to integrate renewables and maintain reliability: ~$250 billion
  - Plus more in flexible backup generation (gas CTs)

- New investments in reliability and resiliency ~ $multi billion per mid-large utility (region-specific)

**Value of Distribution System Investment: Reliability**

Projected SAIDI-x and SAIFI-x
Status Quo Case vs. Incremental Investment Case
Midwestern Electric Utility

\[ SAIDI = \frac{\text{Sum of customer minutes of interruption}}{\text{Number of customers served}} \]

\[ \Delta \text{SAIDI} \rightarrow \Delta \text{CMI} \]

Outage duration profile
Allocation among customer classes
VOLL per class and outage duration

Estimated value of improved SAIDI and SAIFI
NPV when compared to investment schedule

Source:
Based on analysis for midwestern U.S. electric utility.
Value of Distribution System Investment: Resiliency

♦ Investments in resiliency are aimed at bringing service back on line following unavoidable outages (typically caused by extreme weather events)

♦ Frequently involves application of system intelligence and asset hardening
  • Costs tend not be justified on operational grounds alone
  • Cost justification for Smart Grid investments may come load shifting and EE related benefits

♦ Assessing value to customers requires analysis of risk and probabilities, more so than for investments in reliability
  • Outage impacts reduced (if event strikes) and VOLL may well exceed investment costs
  • Similar to insurance products – which are paid for, but my never be called upon
Loss of Electric Service

Major Outage Events

- Insufficient Generation (81) 15%
- Weather & Fire (208) 46%
- Equipment Failure (165) 31%
- Human Error (59) 11%
- Sabotage (16) 3%

All Retail Outages

- Equipment Underground (UG) 22%
- Equipment Overhead (OH) 12%
- Weather 16%
- Tree Related 16%
- Public 8%
- Animal 7%
- Substation 6%
- Transmission 4%
- Utility Error 2%
- Other 7%

G & T: 1 to 5% of Outages

- Average CMI = 1

Distribution: > 95% of Outages

- Average CMI > 100

Source:
1. Lave, Apt and Morgan, Worst Case Electricity Scenarios: The Benefits & Costs of Prevention, CREATE Symposium, University of Southern California, August 2005
2. Breakdown of outage causation between Generation and Distribution: Brattle estimate
Unclear – but unlikely – that investments in reserve requirements and distribution reliability reflect the relative risk of customer outages

- **Generation Reserve Requirements**
  - Value depends on probabilities concerning system demands
  - *Low probability of load shedding (likely ~1%)*

- **Distribution Reliability Investment**
  - Value from reduced outages under normal conditions
  - Majority of “normal” outages associated with distribution ops

- **Distribution Resiliency Investment**
  - Value from reduced outages under extreme conditions
  - Lower probability but wide reaching outage events

- **Outages**
  - ~1% of outages
  - >95% % of outages

Bill Zarakas is an economist who specializes in the electric utility and telecommunications industries. He works extensively on the strategic and regulatory issues facing those industries, and has authored numerous reports, presentations and articles concerning the issues associated with investments in utility infrastructure, costs and benefits relating to system reliability and resiliency, and the evolving factors that are affecting utility business models.

Bill has worked extensively with electric utilities, telecommunications carriers, industry associations, regulatory commissions, and governmental agencies. He has testified before state and federal regulatory commissions and authored reports submitted to governments, regulatory commissions, courts of law, and arbitration panels. He has also headed regulatory audits of utilities and telephone carriers performed on behalf of regulatory commissions.
